## 7 — Abstract —

8 We present an ongoing research on a probabilistic extension of action language  $\mathcal{BC}+$ . Just like  $\mathcal{BC}+$  is  
9 defined as a high-level notation of answer set programs for describing transition systems, the proposed  
10 language, which we call  $p\mathcal{BC}+$ , is defined as a high-level notation of  $\text{LP}^{\text{MLN}}$  programs—a probabilistic  
11 extension of answer set programs.

12 As preliminary results accomplished, we illustrate how probabilistic reasoning about transition sys-  
13 tems, such as prediction, postdiction, and planning problems, as well as probabilistic diagnosis for dy-  
14 namic domains, can be modeled in  $p\mathcal{BC}+$  and computed using an implementation of  $\text{LP}^{\text{MLN}}$ .

15 For future work, we plan to develop a compiler that automatically translates  $p\mathcal{BC}+$  description into  
16  $\text{LP}^{\text{MLN}}$  programs, as well as parameter learning in probabilistic action domains through  $\text{LP}^{\text{MLN}}$  weight  
17 learning. We will work on defining useful extensions of  $p\mathcal{BC}+$  to facilitate hypothetical/counterfactual  
18 reasoning. We will also find real-world applications, possibly in robotic domains, to empirically study the  
19 performance of this approach to probabilistic reasoning in action domains.

## 23 **1** Introduction and Problem Description

24 Action languages, such as  $\mathcal{A}$  [9],  $\mathcal{B}$  [10],  $\mathcal{C}$  [12],  $\mathcal{C}+$  [11], and  $\mathcal{BC}$  [15], are formalisms for describing  
25 actions and their effects. Many of these languages can be viewed as high-level notations of answer set  
26 programs structured to represent transition systems. The expressive possibility of action languages,  
27 such as indirect effects, triggered actions, and additive fluents, has been one of the main research  
28 topics. Most of the extensions accounting for that are logic-oriented, and less attention has been paid  
29 to probabilistic reasoning, with a few exceptions such as [6, 8], let alone automating such probabilistic  
30 reasoning and learning parameters of an action description.

31 Action language  $\mathcal{BC}+$  [2], one of the most recent additions to the family of action languages, is  
32 no exception. While the language is highly expressive to embed other action languages, such as  $\mathcal{C}+$   
33 [11] and  $\mathcal{BC}$  [14], it does not have a natural way to express the likelihood of histories (i.e., a sequence  
34 of transitions).

35 ► **Example 1.** Consider an extension of the robot example from [13]: A robot and a book that can  
36 be picked up are located in a building with 2 rooms  $r_1$  and  $r_2$ . The robot can move to rooms, pick  
37 up the book and put down the book. There is 0.1 chance that it fails when it tries to enter a room,  
38 a 0.2 chance that the robot drops the book when it has the book, and 0.3 chance that the robot fails  
39 when it tries to pick up the book. The robot, as well as the book, was initially at  $r_1$ . It executed the  
40 following actions to deliver the book from  $r_1$  to  $r_2$ : pick up the book; go to  $r_2$ ; put down the book.  
41 However, after the execution, it observes that the book is not at  $r_2$ . What was the problem?

42 To answer the above query, an action language needs the capabilities of not only probabilistic  
43 reasoning, but also abductive reasoning in a probabilistic setting. In my research, we are working on  
44 a probabilistic extension of  $\mathcal{BC}+$ , which we call  $p\mathcal{BC}+$ , with the expressivity to answer queries such  
45 as the one in Example 1. Just like  $\mathcal{BC}+$  is defined as a high-level notation of answer set programs  
46 for describing transition systems,  $p\mathcal{BC}+$  is defined as a high-level notation of  $\text{LP}^{\text{MLN}}$  programs—a  
47 probabilistic extension of answer set programs. Language  $p\mathcal{BC}+$  inherits expressive logical modeling

48 capabilities of  $\mathcal{BC}+$  but also allows us to assign a probability to a sequence of transitions so that we  
49 may distinguish more probable histories.

50 In this paper, as preliminary results accomplished, we will show how probabilistic reasoning  
51 about transition systems, such as prediction, postdiction, and planning problems, can be modeled  
52 in  $p\mathcal{BC}+$  and computed using an implementation of  $\text{LP}^{\text{MLN}}$  [16]. Further, we will show that it can  
53 be used for probabilistic abductive reasoning about dynamic domains, where the likelihood of the  
54 abductive explanation is derived from the parameters manually specified or automatically learned  
55 from the data.

56 For future work, we plan to develop a compiler that automatically translates  $p\mathcal{BC}+$  description  
57 into  $\text{LP}^{\text{MLN}}$  programs, as well as parameter learning in probabilistic action domains through  $\text{LP}^{\text{MLN}}$   
58 weight learning. We will work on defining useful extensions of  $p\mathcal{BC}+$  to facilitate hypothetical/  
59 counterfactual reasoning. We will also find real-world applications, possibly in robotic domains, to  
60 empirically study the performance of this approach to probabilistic reasoning in action domains.

61 This paper will give a summary of my research on  $p\mathcal{BC}+$ , including the background and some  
62 review of existing literature (Section 2), goal of the research (Section 3), the current status of the  
63 research (Section 4), preliminary results accomplished (Section 5) as well as issues and expected  
64 achievements (Section 6).

## 65 **2 Background and Overview of Existing Literature**

### 66 **2.1 Probabilistic Reasoning and Diagnosis in the Context of Action** 67 **Languages**

68 There are various formalisms for reasoning in probabilistic action domains.  $PC+$  [8] is a generalization  
69 of the action language  $\mathcal{C}+$  that allows for expressing probabilistic information.  $PC+$  expresses  
70 probabilistic transition of states through so-called *context variables*, which are exogenous variables  
71 associated with predefined probability distributions.  $PC+$  allows for expressing qualitative and  
72 quantitative uncertainty about actions by referring to the sequence of "belief" states—possible sets of  
73 states together with probabilistic information. On the other hand, the semantics is highly complex  
74 and there is no implementation of  $PC+$  as far as we know.

75 [20] defined a probabilistic action language called  $\mathcal{NB}$ , which is an extension of the (deterministic)  
76 action language  $\mathcal{B}$ .  $\mathcal{NB}$  can be translated into P-log [4] and since there exists a system for computing  
77 P-log, reasoning in  $\mathcal{NB}$  action descriptions can be automated. Like  $PC+$ , probabilistic transitions are  
78 expressed through dynamic causal laws with random variables associated with predefined probability  
79 distribution. In  $\mathcal{NB}$ , however, these random variables are hidden from the action description and are  
80 only visible in the translated P-log representation. In order to translate  $\mathcal{NB}$  into executable low-level  
81 logic programming languages, some semantical assumptions have to be made in  $\mathcal{NB}$ , such as all  
82 actions have to be always executable and nondeterminism can only be caused by random variables.

83 Probabilistic action domains, especially in terms of probabilistic effects of actions, can be  
84 formalized as Markov Decision Process (MDP). The language proposed in [6] aims at facilitating  
85 elaboration tolerant representations of MDPs. The syntax is similar to  $\mathcal{NB}$  and  $PC+$ . The semantics  
86 is more complex as it allows preconditions of actions and imposes less semantical assumption. The  
87 concept of *unknown variables* associated with probability distributions is similar to random variables  
88 in  $\mathcal{NB}$ . There is, as far as we know, no implementation of the language. There is no discussion about  
89 probabilistic diagnosis in the context of the language. PPDDL [19] is a probabilistic extension of the  
90 planning definition language PDDL. Like  $\mathcal{NB}$ , the nondeterminism that PPDDL considers is only the  
91 probabilistic effect of actions. The semantics of PDDL is defined in terms of MDP. There are also  
92 probabilistic extensions of the Event Calculus such as [7] and [18].

93 In the above formalisms, the problem of probabilistic diagnosis is only discussed in [20]. [3] and  
94 [5] studied the problem of diagnosis. However, they are focused on diagnosis in deterministic and  
95 static domains. [13] has proposed a method for diagnosis in action domains with situation calculus.  
96 Again, the diagnosis considered there does not involve any probabilistic measure.

## 2.2 Review: Language $LP^{MLN}$

We review the definition of  $LP^{MLN}$  from [17]. An  $LP^{MLN}$  program is a finite set of weighted rules  $w : R$  where  $R$  is a rule and  $w$  is a real number (in which case, the weighted rule is called *soft*) or  $\alpha$  for denoting the infinite weight (in which case, the weighted rule is called *hard*). An  $LP^{MLN}$  program is called *ground* if its rules contain no variables. We assume a finite Herbrand Universe so that the ground program is finite. Each ground instance of a non-ground rule receives the same weight as the original non-ground formula.

For any ground  $LP^{MLN}$  program  $\Pi$  and any interpretation  $I$ ,  $\bar{\Pi}$  denotes the usual (unweighted) ASP program obtained from  $\Pi$  by dropping the weights,  $\Pi_I$  denotes the set of  $w : R$  in  $\Pi$  such that  $I \models R$ , and  $SM[\Pi]$  denotes the set  $\{I \mid I \text{ is a stable model of } \bar{\Pi}_I\}$ . The *unnormalized weight* of an interpretation  $I$  under  $\Pi$  is defined as

$$W_{\Pi}(I) = \begin{cases} exp\left(\sum_{w:R \in \Pi_I} w\right) & \text{if } I \in SM[\Pi]; \\ 0 & \text{otherwise.} \end{cases}$$

The *normalized weight* (a.k.a. *probability*) of an interpretation  $I$  under  $\Pi$  is defined as

$$P_{\Pi}(I) = \lim_{\alpha \rightarrow \infty} \frac{W_{\Pi}(I)}{\sum_{J \in SM[\Pi]} W_{\Pi}(J)}.$$

Interpretation  $I$  is called a (*probabilistic*) *stable model* of  $\Pi$  if  $P_{\Pi}(I) \neq 0$ . The most probable stable models of  $\Pi$  are the stable models with the highest probability.

## 2.3 Review: Multi-Valued Probabilistic Programs

Multi-valued probabilistic programs [17] are a simple fragment of  $LP^{MLN}$  that allows us to represent probability more naturally.

We assume that the propositional signature  $\sigma$  is constructed from “constants” and their “values.” A *constant*  $c$  is a symbol that is associated with a finite set  $Dom(c)$ , called the *domain*. The signature  $\sigma$  is constructed from a finite set of constants, consisting of atoms  $c = v$ <sup>1</sup> for every constant  $c$  and every element  $v$  in  $Dom(c)$ . If the domain of  $c$  is  $\{\mathbf{f}, \mathbf{t}\}$  then we say that  $c$  is *Boolean*, and abbreviate  $c = \mathbf{t}$  as  $c$  and  $c = \mathbf{f}$  as  $\sim c$ .

We assume that constants are divided into *probabilistic* constants and *non-probabilistic* constants. A multi-valued probabilistic program  $\Pi$  is a tuple  $\langle PF, \Pi \rangle$ , where

■  $PF$  contains *probabilistic constant declarations* of the following form:

$$p_1 :: c = v_1 \mid \cdots \mid p_n :: c = v_n \tag{1}$$

one for each probabilistic constant  $c$ , where  $\{v_1, \dots, v_n\} = Dom(c)$ ,  $v_i \neq v_j$ ,  $0 \leq p_1, \dots, p_n \leq 1$  and  $\sum_{i=1}^n p_i = 1$ . We use  $M_{\Pi}(c = v_i)$  to denote  $p_i$ . In other words,  $PF$  describes the probability distribution over each “random variable”  $c$ .

■  $\Pi$  is a set of rules such that the head contains no probabilistic constants.

The semantics of such a program  $\Pi$  is defined as a shorthand for  $LP^{MLN}$  program  $T(\Pi)$  of the same signature as follows.

■ For each probabilistic constant declaration (1),  $T(\Pi)$  contains, for each  $i = 1, \dots, n$ , (i)  $ln(p_i) : c = v_i$  if  $0 < p_i < 1$ ; (ii)  $\alpha : c = v_i$  if  $p_i = 1$ ; (iii)  $\alpha : \perp \leftarrow c = v_i$  if  $p_i = 0$ .

■ For each rule  $Head \leftarrow Body$  in  $\Pi$ ,  $T(\Pi)$  contains  $\alpha : Head \leftarrow Body$ .

<sup>1</sup> Note that here “=” is just a part of the symbol for propositional atoms, and is not equality in first-order logic.

## 15:4 Probabilistic Action Language $p\mathcal{BC}+$

134 ■ For each constant  $c$ ,  $T(\mathbf{\Pi})$  contains the uniqueness of value constraints

$$135 \quad \alpha : \perp \leftarrow c = v_1 \wedge c = v_2 \quad (2)$$

136 for all  $v_1, v_2 \in \text{Dom}(c)$  such that  $v_1 \neq v_2$ , and the existence of value constraint

$$137 \quad \alpha : \perp \leftarrow \bigvee_{v \in \text{Dom}(c)} c = v. \quad (3)$$

138 In the presence of the constraints (2) and (3), assuming  $T(\mathbf{\Pi})$  has at least one (probabilistic)  
139 stable model that satisfies all the hard rules, a (probabilistic) stable model  $I$  satisfies  $c = v$  for exactly  
140 one value  $v$ , so we may identify  $I$  with the value assignment that assigns  $v$  to  $c$ .

### 141 **3** Goal of the Research

142 The following are our research objectives.

- 143 ■ **Designing Probabilistic Action Language on the Foundation of  $\text{LP}^{\text{MLN}}$**  We design the syntax  
144 and semantics of the language  $p\mathcal{BC}+$  to allow for commonsense reasoning, probabilistic inference  
145 and statistical learning. Furthermore, we study the theoretical properties of the action language to  
146 establish its relation with probabilistic transition systems.
- 147 ■ **Defining the Extension of the Action Language to Explain the Reason of Failure in Dynamic  
148 Domains** We extend the probabilistic action language to account for diagnostic reasoning when  
149 the observation conflicts with the way the system is supposed to behave. This will be in contrast  
150 with diagnostic reasoning in other action languages, which is logical and does not distinguish  
151 which diagnosis is more probable.
- 152 ■ **Extending the Action Language For Hypothetical/Counterfactual Reasoning** We extend the  
153 probabilistic action language to answer queries involving hypothetical/counterfactual reasoning,  
154 where the diagnosis or observation is given, we are interested in how the outcome would have  
155 been affected if some action happened instead.
- 156 ■ **Implementing a Compiler that Automatically Translates  $p\mathcal{BC}+$  Descriptions to  $\text{LP}^{\text{MLN}}$  Programs** Since  $p\mathcal{BC}+$   
157 can be executable through translation to  $\text{LP}^{\text{MLN}}$ , it is desirable to have a  
158 compiler that automates this translation. We plan to develop such a compiler.
- 159 ■ **Empirically Studying the Performance of  $p\mathcal{BC}+$  with Real-World Applications** After we  
160 have the implementation for inference and learning on  $p\mathcal{BC}+$  action descriptions, we will apply  
161  $p\mathcal{BC}+$  on reasoning and learning tasks in real-world applications, possibly robotic domains.

### 162 **4** Current Status of the Research

163 This research is at its starting phase. In our recent paper accepted by ICLP 2018, we have defined the  
164 syntax and semantics of  $p\mathcal{BC}+$ , and experimented with several examples through manual translation  
165 to  $\text{LP}^{\text{MLN}}$ . We have also defined the extension that allows diagnostic reasoning in probabilistic action  
166 domains.

167 Currently we are investigating on parameter learning of  $p\mathcal{BC}+$  through  $\text{LP}^{\text{MLN}}$  weight learning.  
168 We are developing a prototype system for  $\text{LP}^{\text{MLN}}$  weight learning, and several examples of parameter  
169 learning of  $p\mathcal{BC}+$  descriptions are part of the benchmarks we use for the prototype system.

### 170 **5** Preliminary Results Accomplished

171 In this section, we will present the syntax and semantics of  $p\mathcal{BC}+$ , and illustrate how various reasoning  
172 tasks involving probabilistic inference can be automated in this language, through translation to  
173  $\text{LP}^{\text{MLN}}$ .

## 174 5.1 Syntax of $p\mathcal{BC}+$

175 We assume a propositional signature  $\sigma$  as defined in Section 2.3. We further assume that the signature  
 176 of an action description is divided into four groups: *fluent constants*, *action constants*, *pf (probability*  
 177 *fact) constants* and *initpf (initial probability fact) constants*. Fluent constants are further divided into  
 178 *regular* and *statically determined*. The domain of every action constant is Boolean. A *fluent formula*  
 179 is a formula such that all constants occurring in it are fluent constants.

180 The following definition of  $p\mathcal{BC}+$  is based on the definition of  $\mathcal{BC}+$  language.

181 A *static law* is an expression of the form

$$182 \quad \mathbf{caused} \ F \ \mathbf{if} \ G \tag{4}$$

183 where  $F$  and  $G$  are fluent formulas.

184 A *fluent dynamic law* is an expression of the form

$$185 \quad \mathbf{caused} \ F \ \mathbf{if} \ G \ \mathbf{after} \ H \tag{5}$$

186 where  $F$  and  $G$  are fluent formulas and  $H$  is a formula, provided that  $F$  does not contain statically  
 187 determined constants and  $H$  does not contain initpf constants.

188 A *pf constant declaration* is an expression of the form

$$189 \quad \mathbf{caused} \ pf = \{v_1 : p_1, \dots, v_n : p_n\} \tag{6}$$

190 where  $pf$  is a pf constant with domain  $\{v_1, \dots, v_n\}$ ,  $0 < p_i < 1$  for each  $i \in \{1, \dots, n\}$ <sup>2</sup>, and  
 191  $p_1 + \dots + p_n = 1$ . In other words, (6) describes the probability distribution of  $pf$ .

192 An *initpf constant declaration* is an expression of the form (6) where  $pf$  is an initpf constant.

193 An *initial static law* is an expression of the form

$$194 \quad \mathbf{initially} \ F \ \mathbf{if} \ G \tag{7}$$

195 where  $F$  is a fluent formula and  $G$  is a formula that contains neither action constant nor pf constant.

196 A *causal law* is a static law, a fluent dynamic law, a pf constant declaration, an initpf constant  
 197 declaration, or an initial static law. An *action description* is a finite set of causal laws.

198 We use  $\sigma^{fl}$  to denote the set of fluent constants,  $\sigma^{act}$  to denote the set of action constants,  $\sigma^{pf}$  to  
 199 denote the set of pf constants, and  $\sigma^{initpf}$  to denote the set of initpf constants in  $D$ . For any signature  
 200  $\sigma'$  and any  $i \in \{0, \dots, m\}$ , we use  $i : \sigma'$  to denote the set  $\{i : a \mid a \in \sigma'\}$ .

201 By  $i : F$  we denote the result of inserting  $i :$  in front of every occurrence of every constant in  
 202 formula  $F$ . This notation is straightforwardly extended when  $F$  is a set of formulas.

203 ► **Example 2.** The following is an action description in  $p\mathcal{BC}+$  for the transition system shown in  
 204 Figure 1,  $P$  is a Boolean regular fluent constant, and  $A$  is an action constant. Action  $A$  toggles the  
 205 value of  $P$  with probability 0.8. Initially,  $P$  is true with probability 0.6 and false with probability 0.4.  
 206 We call this action description *PSD*. ( $x$  is a schematic variable that ranges over  $\{\mathbf{t}, \mathbf{f}\}$ .)

$$207 \quad \begin{array}{ll} \mathbf{caused} \ P \ \mathbf{if} \ \top \ \mathbf{after} \ \sim P \wedge A \wedge Pf, & \mathbf{caused} \ Pf = \{\mathbf{t} : 0.8, \mathbf{f} : 0.2\}, \\ \mathbf{caused} \ \sim P \ \mathbf{if} \ \top \ \mathbf{after} \ P \wedge A \wedge Pf, & \mathbf{caused} \ Init\_P = \{\mathbf{t} : 0.6, \mathbf{f} : 0.4\}, \\ \mathbf{caused} \ \{P\}^{\text{ch}} \ \mathbf{if} \ \top \ \mathbf{after} \ P, & \mathbf{initially} \ P = x \ \mathbf{if} \ Init\_P = x. \\ \mathbf{caused} \ \{\sim P\}^{\text{ch}} \ \mathbf{if} \ \top \ \mathbf{after} \ \sim P, & \end{array}$$

208 ( $\{P\}^{\text{ch}}$  is a choice formula standing for  $P \vee \neg P$ .)

<sup>2</sup> We require  $0 < p_i < 1$  for each  $i \in \{1, \dots, n\}$  for the sake of simplicity. On the other hand, if  $p_i = 0$  or  $p_i = 1$  for some  $i$ , that means either  $v_i$  can be removed from the domain of  $pf$  or there is not really a need to introduce  $pf$  as a pf constant. So this assumption does not really sacrifice expressivity.

■ **Figure 1** A transition system with probabilistic transitions

## 209 5.2 Semantics of $p\mathcal{BC}+$

210 Given a non-negative integer  $m$  denoting the maximum length of histories, the semantics of an action  
 211 description  $D$  in  $p\mathcal{BC}+$  is defined by a reduction to multi-valued probabilistic program  $Tr(D, m)$ ,  
 212 which is the union of two subprograms  $D_m$  and  $D_{init}$  as defined below.

213 For an action description  $D$  of a signature  $\sigma$ , we define a sequence of multi-valued probabilistic  
 214 program  $D_0, D_1, \dots, D_m$  so that the stable models of  $D_m$  can be identified with the paths in the  
 215 transition system described by  $D$ . The signature  $\sigma_m$  of  $D_m$  consists of atoms of the form  $i : c = v$   
 216 such that

- 217 ■ for each fluent constant  $c$  of  $D$ ,  $i \in \{0, \dots, m\}$  and  $v \in Dom(c)$ ,
- 218 ■ for each action constant or pf constant  $c$  of  $D$ ,  $i \in \{0, \dots, m-1\}$  and  $v \in Dom(c)$ .

219 We use  $\sigma_m^x$ , where  $x \in \{act, fl, pf\}$ , to denote the subset of  $\sigma_m$

$$220 \{i : c = v \mid i : c = v \in \sigma_m \text{ and } c \in \sigma^x\}.$$

221 We define  $D_m$  to be the multi-valued probabilistic program  $\langle PF, \Pi \rangle$ , where  $\Pi$  is the conjunction  
 222 of

$$223 i : F \leftarrow i : G \tag{8}$$

224 for every static law (4) in  $D$  and every  $i \in \{0, \dots, m\}$ ;

$$225 i+1 : F \leftarrow (i+1 : G) \wedge (i : H) \tag{9}$$

226 for every fluent dynamic law (5) in  $D$  and every  $i \in \{0, \dots, m-1\}$ ;

$$227 \{0 : c = v\}^{ch} \tag{10}$$

228 for every regular fluent constant  $c$  and every  $v \in Dom(c)$ ;

$$229 \{i : c = \mathbf{t}\}^{ch}, \{i : c = \mathbf{f}\}^{ch} \tag{11}$$

230 for every action constant  $c$ ; and  $PF$  consists of

$$231 p_1 :: i : pf = v_1 \mid \dots \mid p_n :: i : pf = v_n \tag{12}$$

232 ( $i = 0, \dots, m-1$ ) for each pf constant declaration (6) in  $D$  that describes the probability distribution  
 233 of  $pf$ .

234 In addition, we define the program  $D_{init}$ , whose signature is  $0 : \sigma^{initpf} \cup 0 : \sigma^{fl}$ .  $D_{init}$  is the  
 235 multi-valued probabilistic program

$$236 D_{init} = \langle PF^{init}, \Pi^{init} \rangle$$

237 where  $\Pi^{init}$  consists of the rule

$$238 \perp \leftarrow \neg(0 : F) \wedge 0 : G$$

239 for each initial static law (7), and  $PF^{init}$  consists of

$$240 \quad p_1 :: 0:c = v_1 \mid \dots \mid p_n :: 0:c = v_n$$

241 for each initpf constant declaration (6).

242 We define  $Tr(D, m)$  to be the union of the two multi-valued probabilistic program  
243  $\langle PF \cup PF^{init}, \Pi \cup \Pi^{init} \rangle$ .

244 ► **Example 3.** For the action description  $PSD$  in Example 2,  $PSD_{init}$  is the following multi-valued  
245 probabilistic program ( $x \in \{\mathbf{t}, \mathbf{f}\}$ ):

$$246 \quad \begin{aligned} &0.6 :: 0:Init\_P \mid 0.4 :: 0:\sim Init\_P \\ &\perp \leftarrow \neg(0:P=x) \wedge 0:Init\_P=x. \end{aligned}$$

247 and  $PSD_m$  is the following multi-valued probabilistic program ( $i$  is a schematic variable that ranges  
248 over  $\{1, \dots, m-1\}$ ):

$$249 \quad \begin{array}{ll} 0.8 :: i:Pf \mid 0.2 :: i:\sim Pf & \{i+1:P\}^{ch} \leftarrow i:P \\ i+1:P \leftarrow i:\sim P \wedge i:A \wedge i:Pf & \{i+1:\sim P\}^{ch} \leftarrow i:\sim P \\ i+1:\sim P \leftarrow i:P \wedge i:A \wedge i:Pf & \{i:A\}^{ch} \quad \{i:\sim A\}^{ch} \\ & \{0:P\}^{ch} \quad \{0:\sim P\}^{ch} \end{array}$$

### 250 5.3 $p\mathcal{BC}+$ Action Descriptions and Probabilistic Reasoning

251 In this section, we illustrate how the probabilistic extension of the reasoning tasks discussed in [11],  
252 i.e., prediction, postdiction and planning, can be represented in  $p\mathcal{BC}+$  and automatically computed  
253 using LPMLN2ASP [16]. Consider the following probabilistic variation of the well-known Yale  
254 Shooting Problem: There are two (deaf) turkeys: a fat turkey and a slim turkey. Shooting at a turkey  
255 may fail to kill the turkey. Normally, shooting at the slim turkey has 0.6 chance to kill it, and shooting  
256 at the fat turkey has 0.9 chance. However, when a turkey is dead, the other turkey becomes alert,  
257 which decreases the success probability of shooting. For the slim turkey, the probability drops to 0.3,  
258 whereas for the fat turkey, the probability drops to 0.7.

259 The example can be modeled in  $p\mathcal{BC}+$  as follows:

Notation:  $t$  range over  $\{SlimTurkey, FatTurkey\}$ .

Regular fluent constants:

$Alive(t), Loaded$

Domains:

Boolean

Statically determined fluent constants:

$Alert(t)$

Domains:

Boolean

Action constants:

$Load, Fire(t)$

Domains:

Boolean

Pf constants:

$Pf\_Killed(t), Pf\_Killed\_Alert(t)$

Domains:

Boolean

InitPf constants:

$Init\_Alive(t), Init\_Loaded$

Boolean

**caused**  $Loaded$  **if**  $\top$  **after**  $Load$

**caused**  $Pf\_Killed(SlimTurkey) = \{\mathbf{t} : 0.6, \mathbf{f} : 0.4\}$

**caused**  $Pf\_Killed\_Alert(SlimTurkey) = \{\mathbf{t} : 0.3, \mathbf{f} : 0.7\}$

**caused**  $Pf\_Killed(FatTurkey) = \{\mathbf{t} : 0.9, \mathbf{f} : 0.1\}$

**caused**  $Pf\_Killed\_Alert(FatTurkey) = \{\mathbf{t} : 0.7, \mathbf{f} : 0.3\}$

**caused**  $\sim Alive(t)$  **if**  $\top$  **after**  $Loaded \wedge Fire(t) \wedge \sim Alert(t) \wedge Pf\_Killed(t)$

**caused**  $\sim Alive(t)$  **if**  $\top$  **after**  $Loaded \wedge Fire(t) \wedge Alert(t) \wedge Pf\_Killed\_Alert(t)$

**caused**  $\sim Loaded$  **if**  $\top$  **after**  $Fire(t)$

**default**  $\sim Alert(t)$

**caused**  $Alert(t_1)$  **if**  $\sim Alive(t_2) \wedge Alive(t_1) \wedge t_1 \neq t_2$   
**caused**  $\{Alive(t)\}^{ch}$  **if**  $\top$  **after**  $Alive(t)$ ,  
**caused**  $\{Loaded\}^{ch}$  **if**  $\top$  **after**  $Loaded$   
**caused**  $\{\sim Alive(t)\}^{ch}$  **if**  $\top$  **after**  $\sim Alive(t)$   
**caused**  $\{\sim Loaded\}^{ch}$  **if**  $\top$  **after**  $\sim Loaded$   
**caused**  $\perp$  **after**  $a_1 \wedge a_2$   
**caused**  $Init\_Alive(t) = \{t : 0.5, f : 0.5\}$       **initially**  $Alive(t) = b$  **if**  $Init\_Alive(t) = b$   
**caused**  $Init\_Loaded = \{t : 0.5, f : 0.5\}$       **initially**  $Loaded = b$  **if**  $Init\_Loaded = b$

260 We translate the action description into an LP<sup>MLN</sup> program and use LPMLN2ASP to answer  
 261 various queries about transition systems, such as prediction, postdiction and planning queries.

262 **Prediction** For a prediction query, we are given a sequence of actions and observations that occurred  
 263 in the past, and we are interested in the probability of a certain proposition describing the result of  
 264 the history, or the most probable result of the history. Formally, we are interested in the conditional  
 265 probability  $Pr_{Tr(D,m)}(Result \mid Act, Obs)$  or the MAP inference  $\operatorname{argmax}_{Result} Pr_{Tr(D,m)}(Result \mid$   
 266  $Act, Obs)$ , where  $Result$  is a proposition describing a possible outcome,  $Act$  is a set of facts of the  
 267 form  $i : a$  or  $i : \sim a$  for  $a \in \sigma^{act}$ , and  $Obs$  is a set of facts of the form  $i : c = v$  for  $c \in \sigma^{fl}$  and  
 268  $v \in Dom(c)$ .

269 For example, in the Yale shooting example, such a query could be “Given that only the fat turkey  
 270 is alive and the gun is loaded at the beginning, what is the probability that the fat turkey died after  
 271 shooting is executed?”. To answer this query, we manually translate the action description above into  
 272 the input language of LPMLN2ASP and add the following action and observation as constraints:

```
273 :- not alive("slimTurkey", "f", 0).      :- not alive("fatTurkey", "t", 0).
274 :- not loaded("t", 0).                    :- not fire("fatTurkey", "t", 0).
```

277 Executing the command

```
278 lpmln2asp -i yale-shooting.lpmln -q alive
```

281 yields

```
282 alive('fatTurkey', 'f', 1) 0.700000449318
```

285 **Postdiction** In the case of postdiction, we infer a condition about the initial state given the history.  
 286 Formally, we are interested in the conditional probability  $Pr_{Tr(D,m)}(Initial\_State \mid Act, Obs)$  or  
 287 the MAP inference  $\operatorname{argmax}_{Initial\_State} Pr_{Tr(D,m)}(Initial\_State \mid Act, Obs)$ , where  $Initial\_State$  is a  
 288 proposition about the initial state;  $Act$  and  $Obs$  are defined as above.

289 For example, in the Yale shooting example, such a query could be “Given that the slim turkey was  
 290 alive and the gun was loaded at the beginning, the person shot at the slim turkey and it died, what is  
 291 the probability that the fat turkey was alive at the beginning?”

292 Formalizing the query and executing the command

```
293 lpmln2asp -i yale-shooting.lpmln -q alive
```

296 yields

```
297 alive('fatTurkey', 't', 1) 0.666661211973
```

300 **Planning** In this case, we are interested in a sequence of actions that would result in the highest  
 301 probability of a certain goal. Formally, we are interested in

$$\operatorname{argmax}_{Act} Pr_{Tr(D,m)}(Goal \mid Initial\_State, Act)$$

303 where  $Goal$  is a condition for a goal state, and  $Act$  is a sequence of actions  $a \in \sigma^{act}$  specifying  
 304 actions executed at each timestep.

305 For example, in the Yale shooting example, such query can be “given that both the turkeys are  
 306 alive and the gun is not loaded at the beginning, generate a plan that gives best chance to kill both the  
 307 turkeys with 4 actions”.

308 Formalizing the query and executing the command

```
309 lpmln2asp -i yale-shooting.lpmln
310
```

312 finds the most probable stable model, which yields

```
313 load("t",0) fire("slimTurkey","t",1) load("t",2) fire("fatTurkey","t",3)
314
```

316 which suggests to first kill the slim turkey and then the fat turkey.

## 317 5.4 Extending $p\mathcal{BC}+$ to Allow Diagnosis

318 We define the following new constructs to allow probabilistic diagnosis in action domains. Note  
 319 that these constructs are simply syntactic sugar that does not change the actual expressivity of the  
 320 language.

- 321 ■ We introduce a subclass of regular fluent constants called *abnormal fluents*.
- 322 ■ When the action domain contains at least one abnormal fluent, we introduce a special statically  
 323 determined fluent constant  $ab$  with Boolean domain, and we add  
 324 **default**  $\sim ab$ .
- 325 ■ We introduce the expression

326 **caused<sub>ab</sub>**  $F$  if  $G$  after  $H$

327 where  $F$  and  $G$  are fluent formulas and  $H$  is a formula, provided that  $F$  does not contain statically  
 328 determined constants and  $H$  does not contain initpf constants. This expression is treated as an  
 329 abbreviation of

330 **caused**  $F$  if  $ab \wedge G$  after  $H$ .

331 Once we have defined abnormalities and how they affect the system, we can use

332 **caused**  $ab$

333 to enable taking abnormalities into account in reasoning.

334 We can answer the query in Example 1 by modeling the action domain with this extension. Due  
 335 to lack of space, we skip the details.

## 336 6 Open Issues and Expected Achievements

337 The main open issue is that we do not have a compiler that automates the translation from  $p\mathcal{BC}+$  to  
 338  $LP^{MLN}$ . As illustrated in Section 5.3, the action language  $p\mathcal{BC}+$  can be executable through translation  
 339 to  $LP^{MLN}$ . It is desirable to have a compiler that automates this translation, so that the user can  
 340 directly write  $p\mathcal{BC}+$  descriptions and does not need to worry about the translation detail. We plan to  
 341 develop a compiler that translates action descriptions in  $p\mathcal{BC}+$  into  $LP^{MLN}$  programs automatically.

342 The interface and usage of the compiler will be similar to the system CPLUS2ASP [1], which  
 343 translates the action language  $\mathcal{C}+$  to ASP.

344 Other future works include extending  $p\mathcal{BC}+$  for hypothetical/counterfactual reasoning, exploring  
 345 parameter learning in the setting of probabilistic action language, and empirically studying the  
 346 performance of  $p\mathcal{BC}+$  with weal-world applications.
